Project Overview

In the digital age, information is abundant, but it's fragmented. Students often waste significant cognitive energy hunting for resources across different platforms rather than actually learning.

That's why the project is designed to be a multi-file-type based repository for uploading educational resources from different sources.

The goal is to unify in one site and categorize all the media on the web, in order to let users create and visualize courses joining different media, previously uploaded to the web.

This project arises from the need of students to decapitalize the centralized web-based students repositories by creating a multi-filetype. Allowing users to aggregate, categorize, and sequence diverse media to integrate educational pathways.

Minimum Viable Implementation

The core objective of the initial phase is to establish a functional version of our project. It includes the most important features:

Database and Data

- **Database Schema:** Full implementation of the tables defined in the logical model.
- **Media Management:** Manage and save media files.
- **Votes:** Let users give “upvotes” to the content they like.

User Interface and Views

- **Authentication:** A page for users to create an account and sign in
- **Content Discovery:** A main grid to see all shared posts.
- **Content Creation** (media and project): A way for users to publish their own media or projects. Being the way to publish media a framework block.
- **Detail Pages** (media and project): Special pages to see all the information about a file or project. There the users can comment on each other's posts, being the comment section a framework block.

Future Extensions

- **User Profile View:** A personal page for each user to see their information, their uploaded files and their activity on the site.
- **View counts:** A counter to show how many times each file or project has been seen.
- **Category Tags:** A system to organize content into groups, for example: UdL > Programming > Python.
- **User View History:** A list where users can see the files they have visited recently.
- **Comment Replies:** A way for users to reply directly to other people's comments. We have designed the logic model already prepared for this extension.
- **Report Content System:** A tool for users to report content that is wrong or inappropriate. We have designed the logic model already prepared for this extension.
- **Report Users System:** A tool for users to report other users.
- **Privacy Settings:** Options to make a post Public, Private or Hidden from other users.
- **University Integrations:** Connect our platform with official university systems using their APIs.
- **File Previews:** Use external APIs to show a small version of the file before the user downloads it.

Logic Model

There are some aspects of the logical model that are implemented for future extensions (comment replies and report content system).

Solution Design

Technology Stack:

- Framework: Django (Python)
- Database: PostgreSQL
- Storage: Local Storage
- Frontend: Django Templates + CSS/Bootstrap
